TITLE: Investigation of the compression process during sintering in the presence of a liquid phase

PERIODICAL: Poroshkovaya Metallurgia, no.4, 1962, 72-89

TEXT: The sintering of metal powders in the present of a liquid phase has so far been little investigated. The kinetics of such processes may considerably differ from those which take place during the sintering of solid metal powders. Three different mechanisms of sintering in the presence of a liquid phase are considered: The kinetics of sintering W-Cu and TiC-Ni powders under the above conditions were investigated by means of a dilatometric device. The density of the W-Cu metal powder increases sharply with the temperature of sintering and reaches a maximum value at 1300° - 1350°C. This increase in density is probably due to the increase in wetting of the tungsten by copper. A complete compression in the TiC-Ni metal powder is achieved when the content of the liquid phase is not less than 20-25 vol%. There are 12 figures and 2 tables.

Discr: 4E2c

Discussion concerning surface treatments and the possibilities of their application to mechanisms working at elevated temps. Jiri Nainar, *Materiálový Sborník* 1958, 183-91 (Pub. 1958). A survey is given of the main factors which influence fretting and wear of metals under sliding friction at higher temps. Possible methods able to increase the resistance of materials to fretting and wear by adequate treatment are indicated and evaluated. The results of lab. fretting tests on steels designed to work at higher temps. are listed. Part of the tested materials has been surface treated, by using hard Cr plating, nitriding, diffusion sulfuring or sclerizing, and Ag plating. Coeffs. of dry sliding friction and the relative resistance of various pairs of materials to fretting have been stated, by using a speed of 0.0284 m./sec., temp. up to 600°, and specific pressures up to 1400 lb./sq. in. TITLE: Investigation of the friction properties of  
sulphonitrided surfaces

PERIODICAL: Strojírenství, 1961, Vol.11, No.10, p.79<sup>4</sup>

TEXT: The report covers a part of a comprehensive project on "Investigation of sulphonitrided layers with a high resistance against seizing" and deals with investigation of the friction characteristics of sulphonitrided surfaces which are treated according to various methods, both in a bath and in a gaseous medium. In the tests the following materials were investigated according to the specification ČSN:12 013 (behanite), 12 060, 15 241 (Poldi CVZ) and 42 2424 (inoculated grey iron). A description is given of the equipment and of the test methods used. The relative resistance against seizing of the investigated materials after various treatments of the rubbing surfaces was determined and the achieved results are summarised. ✓

TITLE: Method of making the friction surfaces of machine parts from metallic materials

SOURCE: Hutnicke listy, no. 3, 1964, 227

TOPIC TAGS: friction surface, machine part, iron alloy, diffuse sulfurizing, selenizing, nitridizing, friction-resistant layer, carbon steel, low-alloy steel, gray cast iron

ABSTRACT: The invention concerns a method of making friction surfaces of machine parts from iron alloys by diffuse sulfurizing, selenizing or nitridizing or a combination of them, whereby boron with a concentration of at least 0.05% by volume in the active medium can be simultaneously diffused into the part. In creating diffuse surface layers in the liquid medium, the usual means are used for sulfonitridation, nitridation or nitrocementation, to which are added boron compounds that are liquid at the temperature of the process, e.g. of the  $BH_3$  type, in the

proportion 200:1 to 10:1. The whole process takes place at over 300C, lasting 1/2 to about 30 hours, according to the desired thickness of the layer of material treated and the process used in the production proper. The method produces harder and very friction-resistant layers, especially in carbon and low-alloy steels and gray cast iron.
